EC2 Monitoring Tool

QUICK START GUIDE | Classmate testing

Before you begin: You need Windows with Git Bash, a running EC2 lab instance, and its matching downloaded .pem SSH key. The GitHub repository is public, so you can clone the project without requesting access.

1 Download the project to your Desktop (first time only)

Open **Git Bash on your Windows computer**, then run:

```
cd ~/Desktop
git clone https://github.com/jk377y/ec2-monitoring-tool.git "EC2 Monitoring Tool"
```

This creates the **EC2 Monitoring Tool** folder on your Desktop. If you already downloaded it, skip cloning and see **Updating the project** below.

2 Start your AWS lab and get the connection details

Start an **Amazon Linux EC2** lab instance. From the lab credentials page, copy its **public IPv4 address** and download the matching **.pem** SSH private key.

Check that SSH access on **TCP port 22** is permitted from your current network. You do **not** need AWS access keys, a .ppk file, S3, or CloudWatch for this tool.

3 Put your PEM file in the project folder

Move the downloaded **.pem** file into **Desktop / EC2 Monitoring Tool** (next to **start.sh**). In local Git Bash, check that it is there:

```
cd ~/Desktop/"EC2 Monitoring Tool"
ls *.pem
```

The launcher automatically runs **chmod 400** on the selected PEM file. Keep the private key to yourself; never upload it to GitHub or send it to classmates.

4 Launch the tool

```
bash start.sh
```

At the prompts: enter your **current EC2 public IP**; press **Enter** to use **ec2-user** (or type another username); press **Enter** to accept **labsuser.pem** if that is the suggested file, or type the exact name of your PEM.

If more than one PEM is in the folder, be sure to select the one for this lab session.

5 Watch the dashboard and finish

The script checks the connection, uploads the files, starts monitoring, and opens the dashboard in your **default browser**. Leave that Git Bash terminal open while using the dashboard.

```
http://127.0.0.1:8080/index.html
```

When finished, press **Ctrl+C** in the launcher terminal to close the SSH tunnel. This does **not** terminate your EC2 instance or stop the remote collector. End your AWS lab when you are done.

Updating the project later: Open Git Bash and run the following **before** launching a new session. No need to clone a second time.

```
cd ~/Desktop/"EC2 Monitoring Tool"
git pull
```

Quick checks: No SSH connection? Check the current IP, username, matching PEM and port 22 access. No browser tab? Open the dashboard URL above manually. Port 8080 already in use? Close an earlier SSH tunnel with Ctrl+C. Please share any errors or feedback with the project owner.
